Aim: Implementation of Support Vector Machine Algorithm.

Objective: Ability to perform various feature engineering tasks, apply Support Vector Machine and create the Confusion Matrix.

Theory:

The goal of the SVM algorithm is to create the best line or decision boundary that can segregate n-dimensional space into classes so that we can easily put the new data point in the correct category in the future. This best decision boundary is called a hyperplane.

SVM chooses the extreme points/vectors that help in creating the hyperplane. These extreme cases are called as support vectors, and hence algorithm is termed as Support Vector Machine. Consider the below diagram in which there are two different categories that are classified using a decision boundary or hyperplane:

Hyperplane and Support Vectors in the SVM algorithm:

Hyperplane: There can be multiple lines/decision boundaries to segregate the classes in n-dimensional space, but we need to find out the best decision boundary that helps to classify the data points. This best boundary is known as the hyperplane of SVM.

The dimensions of the hyperplane depend on the features present in the dataset, which means if there are 2 features (as shown in image), then hyperplane will be a straight line. And if there are 3 features, then hyperplane will be a 2-dimension plane.

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

We always create a hyperplane that has a maximum margin, which means the maximum distance between the data points.

Support Vectors:

The data points or vectors that are the closest to the hyperplane and which affect the position of the hyperplane are termed as Support Vector. Since these vectors support the hyperplane, hence called a Support vector.

Implementation of Support Vector Machine

1. Data Pre-processing step
2. Fitting the SVM classifier to the training set
3. Predicting the test set result
4. Creating the confusion matrix
5. Visualizing the training set result
6. Visualizing the test set result

Implementation:

```
import numpy as np
```

```
from sklearn.model_selection import train_test_split
```

```
from sklearn import datasets
```

```
class SVM:
```

```
    def __init__(self, learning_rate=0.001, lambda_param=0.01, n_iters=1000):
```

```
        self.lr = learning_rate
```

```
        self.lambda_param = lambda_param
```

```
        self.n_iters = n_iters
```

```
        self.w = None
```

```
        self.b = None
```

```
    def fit(self, X, y):
```

```
        n_samples, n_features = X.shape
```

```
        y_ = np.where(y <= 0, -1, 1)
```

```
# Weights Initialization
```

```
self.w = np.zeros(n_features)
```

```
self.b = 0
```

```
for _ in range(self.n_iters):
```

```
    for idx, x_i in enumerate(X):
```

```
        condition = y_[idx] * (np.dot(x_i, self.w) - self.b) >= 1
```

```
        if condition:
```

```
            self.w -= self.lr * (2 * self.lambda_param * self.w)
```

```
        else:
```

```
            self.w -= self.lr * (2 * self.lambda_param * self.w - np.dot(x_i, y_[idx]))
```

```
            self.b -= self.lr * y_[idx]
```

```
def predict(self, X):
```

```
    approx = np.dot(X, self.w) - self.b
```

```
    return np.sign(approx)
```

```
if __name__ == "__main__":
```

```
    X, y = datasets.make_blobs(
```

```
        n_samples=50, n_features=2, centers=2, cluster_std=1.05, random_state=40
```

```
    )
```

```
    y = np.where(y == 0, -1, 1)
```

```
    X_train, X_test, y_train, y_test = train_test_split(
```

```
        X, y, test_size=0.2, random_state=123
```

```
    )
```

```
    clf = SVM()
```

```
    clf.fit(X_train, y_train)
```

Department of Artificial Intelligence & Data Science

```
predictions = clf.predict(X_test)
```

```
def accuracy(y_true, y_pred):
```

```
    accuracy = np.sum(y_true == y_pred) / len(y_true)
```

```
    return accuracy
```

```
print(f"SVM classification accuracy : {accuracy(y_test, predictions)}")
```

```
SVM classification accuracy : 1.0
```

Conclusion:

In conclusion, the implementation of the Support Vector Machine (SVM) algorithm demonstrates its capability to classify data points by creating a hyperplane with maximum margin, aided by support vectors. The provided code defines an SVM class with methods for fitting the classifier to training data and predicting outcomes for test data. Additionally, the accuracy of the SVM classification is evaluated using a custom accuracy function. This showcases the effectiveness of SVM in binary classification tasks, highlighting its importance in various real-world applications where clear decision boundaries are essential for accurate predictions.
